16. Abstract The QCSEE Program provides for the design, fabrication, and testing of two experimental high bypass geared turbofan engines and propulsion systems for short-haul passenger aircraft. The overall objective of the program is to develop the propulsion technology required for future externally blown flap types of aircraft with engines located both under-the-wing and over-the-wing. This report covers the aerodynamic and mechanical preliminary design of the QCSEE over-the-wing 1.36 pressure ratio fan. Design information is given for both the experimental and flight designs.

SECTION 1.0

OTW FAN DESIGN

1.1 SUMMARY

An Under-the Wing and an Over-the Wing fan rotor will be built and tested as part of the NASA QCSEE program.

The aerodynamic design of both the variable-pitch UTW and fixed-pitch OTW geared fans was completed during the Preliminary Design Phase.

At the major operating conditions of takeoff and maximum cruise, a corrected flow of 405.5 kg/sec (894 lbm/sec) was selected for both fans which enables common inlet hardware to yield the desired 0.79 average throat Mach number at the critical takeoff noise measurement condition. The aerodynamic design bypass pressure ratio is 1.34 for the UTW and 1.36 for the OTW which is intermediate between the takeoff and maximum cruise power settings. The takeoff pressure ratios are 1.27 for the UTW and 1.34 for the OTW. The takeoff corrected tip speeds are 289 m/sec (950 ft/sec) for the UTW and 354 m/sec (1162 ft/sec) for the OTW. These pressure ratios and speeds were selected on the basis of minimum noise within the constraints of adequate stall margin and core engine supercharging.

The OTW fan employs 28 fixed-pitch fan blades. A flight version of the design would use composite fan blades, but titanium fan blades will be used in the experimental fan as a cost saving measure. The conceptual design with composite blades was used to establish the number of fan blades, and in conjunction with the aerodynamic design, the blade airfoil shape. The metal blades require a larger fan disk rim than would be required for composite blades. The fan disk support cone and the remaining fan components on the experimental engine will be of flight design.

SECTION 2.0

OTW FAN AERODYNAMIC DESIGN

2.1 OPERATING REQUIREMENTS

The major operating requirements for the over-the-wing (OTW) fan, Figure 1, are takeoff, where noise and thrust are of primary importance, and maximum cruise, where economy and thrust are of primary importance. A secondary requirement was to utilize hardware common to the UTW fan when no significant performance penalty was involved. At takeoff, a low fan pressure ratio of 1.34 was selected to minimize the velocity of the bypass stream at nozzle exit. A corrected flow of 405.5 kg/sec (894 lb/sec), the same as for the UTW, at this pressure ratio yields the required engine thrust. The inlet throat is sized at this condition for an average Mach number of 0.79 to minimize forward propagation of fan noise. This sizing of the inlet throat prohibits higher corrected flow at altitude cruise. The required maximum cruise thrust is obtained by raising the fan pressure ratio to 1.38. The aerodynamic design point was selected at an intermediate condition, which is a pressure ratio of 1.36 and a corrected flow of 408 kg/sec (900 lb/sec). Table I summarizes the key parameters for these three conditions.

Table I. QCSEE OTW Fan.			
Parameter	Design Point	Takeoff	Maximum Cruise
Total fan flow	408 kg/sec (900 lb/sec)	405.5 kg/sec (894 lb/sec)	405.5 kg/sec (894 lb/sec)
Pressure ratio - bypass flow	1.36	1.34	1.38
Pressure ratio - core flow	1.43	1.43	1.44
Bypass ratio	9.9	10.1	9.8
Corrected tip speed	358 m/sec (1175 ft/sec)	354 m/sec (1162 ft/sec)	359 m/sec (1178 ft/sec)

2.2 BASIC DESIGN FEATURES

A cross section of the selected OTW fan configuration is shown in Figure 2. The fan outer flowpath, vane-frame including outer and inner flowpath, and transition duct including the six frame struts are all common to the UTW fan configuration. Thus the integrated nacelle vane-frame assembly is common to both propulsion systems. There are 28 fixed-pitch rotor blades. The overall proportions for the rotor blades, blade number, and radial distributions of thickness and chord were selected to provide a satisfactory aeromechanical flight-type composite configuration. However, to minimize overall program costs, titanium was substituted for the actual blade construction. The stall

Figure 1. Major Operating Requirements for OTW Fan.

Figure 2. Cross Section of OTW Fan.

margin for the OTW fan is projected to be adequate. The circumferential grooved casing treatment, however, can be retained from the UTW fan to provide added protection against stall. The rotor was positioned axially such that the trailing edge hub intersects the hub flowpath at the same axial station as the UTW which puts the aft face of the fan disk at approximately the same engine station. A tip axial spacing between rotor trailing edge and vane-frame leading edge equal to 1.9 true rotor tip chords results. The vane-blade ratio is 1.18. Immediately following the rotor, in the hub region, is a splitter which divides the flow into the bypass portion and core portion. The proximity of the splitter leading edge to the rotor blade is to enable additional design control on the streamlines in the hub region to provide improved surface velocity and loading distributions. The 156 OGV's for the fan hub, or core portion, flow are in the annular space under the splitter. There are six struts in the gooseneck which guides the fan hub flow into the core compressor.

In the vane-frame, which is common with the UTW Fan, the vanes are non-axisymmetric in that five vane geometries, each with a different camber and stagger, are employed around the annulus. This nonaxisymmetric geometry is required to conform the vane-frame downstream flow field to the geometry of the pylon, which protrudes forward into the vane-frame, and simultaneously maintains a condition of minimum circumferential static pressure distortion upstream of the vane-frame. There are 33 vanes in the vane-frame which yield a vane-blade ratio of 1.18.

2.3 DETAILED CONFIGURATION DESIGN

The corrected tip speed at the aerodynamic design point was selected at 358 m/sec (1175 ft/sec). This was selected for design purposes, as a compromise between the takeoff and cruise tip speed requirements. The objective design point adiabatic efficiency is 88% for the bypass portion and 78% for the core portion. Requirements include 16% stall margin at takeoff and high fan hub pressure ratio to provide good core engine supercharging. An inlet radius ratio of 0.42 was selected, compared to 0.44 for the UTW fan, to provide additional annulus area convergence at rotor hub which reduces the hub aerodynamic loading. Discharge radius ratios are approximately the same for the two fans. For the 1.803 m (71.0 in.) tip diameter, a flow per annulus area of 194 kg/sec-m^2 (39.8 lb/sec-ft^2) results.

The standard General Electric axisymmetric flow computation procedure was employed in calculating the velocity diagrams. Several calculation stations were included internal to the rotor blade to improve the overall accuracy of the solution in this region. The physical splitter geometry is represented in the calculations. Forward of the splitter, calculation stations span the radial distance from OD to ID. Aft of the splitter, calculation stations span the radial distance between the OD and the topside of the splitter and between the underside of the splitter and the hub contour. At each calculation station effective area coefficients consistent with established design practice were assumed.

The design radial distribution of rotor total pressure ratio is shown in Figure 3. This distribution is consistent with a stage average pressure ratio of 1.36 in the bypass region. The higher than average pressure ratio

Figure 3. OTW Radial Distribution of Rotor Total Pressure Ratio.

in the hub region provides maximum core engine supercharging subject to a balance between the constraints of acceptable rotor diffusion factors, stator inlet absolute Mach numbers, and stator diffusion factors. A stage average pressure ratio of 1.43 results at the core OGV exit. The assumed radial distribution of rotor efficiency for the design is shown in Figure 4 which was based on measured results from similar configurations (Quiet Engine, Fan B). The assumption of efficiency rather than total-pressure-loss coefficient is a General Electric design practice for rotors of this type. The radial distribution of rotor diffusion factor which results from these assumptions is shown in Figure 5. Figures 6 and 7 show the radial distributions of rotor relative Mach number and air angle, respectively. At the rotor hub the flow turns 16° past axial which corresponds to a work coefficient of 2.6.

The assumed radial distribution of total-pressure-loss coefficient for the core portion OGV is shown in Figure 8. The relatively high level, particularly in the ID region, is in recognition of the very high bypass ratio of the OTW engine and, accordingly, the small relative size of the core OGV compared to the rotor. The annulus height of the core stator is approximately 70% of the rotor staggered spacing, a significant dimension when analyzing secondary flow phenomena. It is anticipated that a significant portion of the core OGV will be influenced by the rotor secondary flows. The moderately high core OGV diffusion factors, turning angles, and inlet Mach numbers, as shown in Figure 8, were contributing factors in the total-pressure-loss coefficient assumptions. An average swirl of 6° is retained in the fluid at exit from the core OGV, like the UTW configuration. This was done to lower its aerodynamic loading. The transition duct struts designed for the UTW configuration were cambered to accept this swirl.

A tabulation of significant blade element parameters for the OTW design is presented in Table II.

2.4 ROTOR BLADE DESIGN

The rotor blade tip solidity was selected as 1.3. With a rotor tip inlet relative Mach number of 1.22, a reduction in tip solidity would lower the overall performance potential of the configuration. The rotor hub solidity was selected as 2.2. The primary factors in this selection were the rotor hub loading and sufficient passage length to do the required 56° turning. The radial chord distribution is linear with radius. Mechanical input was provided to ensure that this chord distribution and the selected thickness distribution, as shown in Figures 9 and 10, produced a satisfactory aeromechanical configuration.

The detailed layout procedure employed in the design of the fan blade geometry generally parallels established design procedures. In the tip region of the blade where the inlet relative flow is supersonic, the uncovered portion of the suction surface was set to ensure that the maximum flow passing capacity is consistent with the design flow requirement. The incidence angles in the tip region were selected according to transonic blade design practice which has

NOMENCLATURE FOR TABULATION

HEADING	IDENTIFICATION	ENGLISH UNITS
GENERAL		
SL	STREAMLINE NUMBER	-
PSI	STREAM FUNCTION	-
RADIUS	STREAMLINE RADIUS	IN.
% IMM	PERCENT IMMERSION FROM OUTER HALL	%
Z	AXIAL DIMENSION	IN.
BLKAGE	ANNULUS BLOCKAGE FACTOR	-
FLOW	WEIGHT FLOW	LBM/SEC
ANGLES AND MACH NUMBERS		
PHI	MERIDIONAL FLOW ANGLE	DEG.
ALPHA	ABSOLUTE FLOW ANGLE $= \arctan (C_U/C_Z)$	DEG.
BETA	RELATIVE FLOW ANGLE $= \arctan (-W_U/C_Z)$	DEG.
M-ABS	ABSOLUTE MACH NUMBER	-
M-REL	RELATIVE MACH NUMBER	-
VELOCITIES		
C	ABSOLUTE VELOCITY	FT/SEC
W	RELATIVE VELOCITY	FT/SEC
CZ	AXIAL VELOCITY	FT/SEC
U	BLADE SPEED	FT/SEC
CU	TANGENTIAL COMPONENT OF C	FT/SEC
WU	TANGENTIAL COMPONENT OF W	FT/SEC
FLUID PROPERTIES		
PT	ABSOLUTE TOTAL PRESSURE	LB/SG, IN.
TT	ABSOLUTE TOTAL TEMPERATURE	DEG-R
TT-REL	RELATIVE TOTAL TEMPERATURE	DEG-R
PS	STATIC PRESSURE	LB/SG, IN.
TS	STATIC TEMPERATURE	DEG-R
RHO	STATIC DENSITY	LBM/CU, FT.
EFF	CUMULATIVE ADIABATIC EFFICIENCY REFERENCED TO PTI, TTI	-
PTI	INLET ABSOLUTE TOTAL PRESSURE	LB/SG, IN.
TTI	INLET ABSOLUTE TOTAL TEMPERATURE	DEG-R
AERODYNAMIC BLADING PARAMETERS		
TPLC	TOTAL PRESSURE LOSS COEFFICIENT	-
PR-ROM	TOTAL PRESSURE RATIO ACROSS BLADE ROW	-
DEL-T	TOTAL TEMPERATURE RISE ACROSS ROTOR	DEG-R
D	DIFFUSION FACTOR	-
DP/D	STATIC PRESSURE RISE COEFFICIENT	-
CZ/CZ	AXIAL VELOCITY RATIO ACROSS BLADE ROW	-
SOLIDTY	SOLIDITY	-
R-AVG	AVERAGE STREAMLINE RADIUS ACROSS BLADE ROW	IN.
F-TAN	TANGENTIAL BLADE FORCE PER UNIT BLADE LENGTH	LB/IN
F-AXL	AXIAL BLADE FORCE PER UNIT BLADE LENGTH	LB/IN
F-COEF	FLOW COEFFICIENT $= C_Z/U_1$	-
T-COEF	WORK COEFFICIENT $= (2*G*J*CP*DEL-T)/(U_2*U_2)$	-

Figure 9. OTW Rotor Chord Distribution.

Figure 10. OTW Rotor Thickness Distribution.

yielded good overall performance for previous designs. In the hub region, where the inlet flow is subsonic, incidence angles were selected from NASA cascade data correlations with adjustments from past design experience. The blade trailing edge angle was established by the deviation angle which was obtained from Carter's Rule applied to the camber of an equivalent two-dimensional cascade with an additive empirical adjustment, X . This adjustment is derived from aerodynamic design and performance synthesis for this general type of rotor. However, in the rotor hub, the significant turning past axial results in profile shapes that resemble impulse turbine blades. Design practice in turbine blade layout suggested that blade sections using the full empirical adjustment would result in an overturning of the flow. This overturning by the rotor would aggravate a relatively high-Mach-number-high-loading condition on the core OGV. Consequently the empirical adjustment was reduced 2° in this region. The incidence and deviation angles and the empirical adjustment angle employed in the design are shown in Figure 11.

Over the entire blade span, the minimum passage area, or throat, must be sufficient to pass the design flow including allowances for boundary layer losses, and flow nonuniformities. In the transonic and supersonic region the smallest throat area, consistent with permitting the design flow to pass, is desirable since this minimizes overexpansions on the suction surface. A further consideration was to minimize disturbances to the flow along the forward portion of the suction surface to minimize forward propagating waves that might provide an additional noise source. Design experience guided the degree to which each of these desires was applied to individual section layouts. The percent throat margin, the percentage by which the ratio of the effective throat area to the capture area exceeds the critical area ratio, is shown in Figure 12. The values employed are generally consistent with past experience.

The resulting blade shapes have very little camber in the tip region. In the mid-span region, the shapes generally resemble multiple circular arc sections with the majority of the camber occurring in the aft portion. In the inner region, the shapes are similar to a double circular arc. Figure 13 shows plane sections through the blade at several radial locations. The resulting camber and stagger radial distributions are shown in Figure 14.

Table III gives the detailed coordinate data (in inches) for the blade sections shown in Figure 13. The coordinate center is at the stacking axis.

2.5 CORE OGV DESIGN

A moderately low aspect ratio of 1.3 was selected for the core portion OGV to provide a rugged mechanical system. This selection was in recognition of the potentially severe aeromechanical environment of the core OGV, i.e., large rotor blade wakes, because of its small size in relationship to that of the rotor blade. A solidity at the ID of 2.24 was selected to yield reasonable levels of diffusion factor, Figure 8. The number of OGV's which result is 156.

Profiles for the core OGV are multiple circular arcs. The incidence angle over the outer portion of the span was selected from a correlation of the NASA low-speed cascade data. Locally, in the ID region, the incidence angle was

reduced 4° . This local reduction in incidence was in recognition of traverse data results on other high bypass fan configurations which show core stator inlet air angles several degrees higher than the axisymmetric calculated values. The deviation angle was obtained from Carter's Rule as was described for the rotor blade, but no empirical adjustment was made. The resulting incidence and deviation angles are shown in Figure 15. An average throat area 5% greater than the critical contraction ratio was employed in the design. The throat area margin is shown in Figure 15. Locally, in the ID region, the margin is zero for the axisymmetric vector diagrams. However, as noted above, the anticipated inlet air angle in this region will be several degrees higher, and therefore the capture area will be several percent lower than the axisymmetric calculation. The effective throat-to-capture area ratio will therefore increase to provide adequate margin.

The multiple circular arc mean line consisted of a maximum radius arc forward of the throat, which occurs at the passage leading edge. This arc was determined by the incidence and throat area selection. A small blend region transitioned into a second arc prescribed by the overall camber requirement. The resulting radial distributions of camber, stagger, solidity, chord, and thickness-to-chord ratio are given in Figure 16. Figure 17 is a cylindrical section of the OGV at the pitch line radius. The coordinates for this section are given in Table IV. The coordinate data are in inches.

2.6 TRANSITION DUCT STRUT DESIGN

The transition duct flowpath is shown in Figure 18. It is common to both the UTW and OTW engines. The ratio of duct exit to duct inlet flow area is 1.02. There are six struts in the transition duct which are aerodynamically configured to remove the 0.105 radian (6°) of swirl left in the air by the core OGV's and to house the structural spokes of the composite wheels (see Figure 2). In addition, at engine station 196.5 (Figure 2), the 6 and 12 o'clock strut positions must house radial accessory drive shafts. The number of struts and axial position of the strut trailing edge were selected identical with the F101 engine to minimize unknowns in the operation of the core engine system. The axial positions and thickness requirements of the composite wheel spokes were dictated by mechanical considerations. The axial location of the strut leading edge at the OD was determined by its proximity to the splitter leading edge in the UTW engine configuration. At the OD flowpath, the strut leading edge is 17.8 mm (0.7 in.) forward of the wheel spoke. A relatively blunt strut leading edge results from the 26.7 mm (1.05 in.) wheel spoke thickness requirement. The wheel spoke is radial. The axial lean of the strut leading edge provides relief from the LE bluntness at lower radii and makes the LE approximately normal to the incoming flow. A NASA 65-series thickness distribution was selected for the basic profile thickness which was modified for the special considerations required in this design. The strut thickness is the same for all radii aft of the forward wheel spoke LE (Figure 18) to facilitate fabrication. A cylindrical cut cross section showing the nominal strut geometry at three radii is shown in Figure 19. The thickness distribution for the 6 and 12 o'clock struts was further modified for the

Transition Duct Strut Nominal Geometry
(4 Struts Required)

Figure 19. Transition Duct Strut.

envelope of the radial drive shaft. Cylindrical cut cross sections of these struts are also shown in Figure 19. The leading edge 40% chord of these further modified sections is identical to that of the nominal strut geometry, and aft of forward wheel spoke LE, the strut thickness is the same for all radii. The core engine has demonstrated operation in the presence of a similar thick strut in the F101 application without duress.

2.7 VANE-FRAME DESIGN

The vane-frame performs the dual function of an outlet guide vane for the bypass flow and a frame support for the engine components and nacelle. It is a common piece of hardware for both the UTW and OTW engine fans. It is integrated with the pylon which houses the radial drive shaft at engine station 196.50 (see Figure 2), houses the engine mount at approximately engine station 210, provides an interface between the propulsion system with the aircraft system, and houses the forward thrust links. The vane-frame furthermore acts as an inlet guide vane for the UTW fan when in the reverse mode of operation.

A conventional OGV system turns the incoming flow to axial. The housing requirements of the pylon dictate a geometry which requires the OGV's to underturn approximately 0.174 radian (10°) on one side and to overturn approximately 0.174 radian (10°) on the other side. The vanes must be tailored to downstream vector diagrams which conform to the natural flow field around the pylon to avoid creating velocity distortions in the upstream flow. Ideally, each vane would be individually tailored. However, to avoid excessive costs, five vane geometry groups were selected as adequate.

The Mach number and air angle at inlet to the vane-frame are shown in Figure 20 for both the UTW and OTW fans. In the outer portion of the bypass duct annulus, the larger air angle in the UTW environment results in a less negative incidence angle for it than for the OTW environment. The Mach number in the outer portion of the annulus is also higher in the UTW environment. When selecting incidence angles, a higher Mach number environment naturally leads to the desire to select a less negative incidence angle. The amount by which the incidence angle would naturally be increased due to the higher Mach number UTW environment is approximately equal to the increase in the inlet air angle of the UTW environment. In the inner portion of the annulus, the inlet Mach number and air angle are higher for the OTW environment. The natural increase in incidence angle desired because of the higher Mach number is approximately the same as the increase in the inlet air angle. As a result of these considerations, no significant aerodynamic performance penalty is assessed to using common hardware for both the UTW and OTW fans.

Locally, near the bypass duct ID, there is a discontinuity in the aerodynamic environment of the UTW configuration. This discontinuity represents that portion of the flow which passes under the island but bypasses the splitter. The calculation ignored mixing across the vortex sheet. In the design of the vane geometry no special considerations were incorporated because of this discontinuity since it is believed that in a real fluid the mixing process will greatly diminish the vortex strength.

Figure 20. Vane Frame Aerodynamic Environment.

The vane chord at the OD was selected largely by the mechanical requirement of axial spacing between the composite frame spokes. At the ID the vane leading edge was lengthened primarily to obtain an aerodynamically reasonable leading edge fairing on the pylon compatible with the envelope requirements of the radial drive shaft. The ID region is significantly more restrictive in this regard because of choking considerations, particularly for the OTW environment, with the reduced circumferential spacing between vanes. The solidity resulting from 33 vanes, an acoustic requirement, was acceptable from an aerodynamic loading viewpoint as shown in Figure 21. The two diffusion factor curves are a result of the two aerodynamic environments, UTW and OTW, to which the common vane frame geometry is exposed. The thickness is a modified NASA 65-series distribution. Maximum-thickness- and trailing-edge-thickness-to-chord ratios of 0.08 and 0.02, respectively, were selected at the OD. The same maximum thickness and trailing edge thickness were used at all other radii which results in maximum-thickness- and trailing-edge-thickness-to-chord ratios of 0.064 and 0.016, respectively, at the ID.

As a guide in the selection of the overall vector diagram requirements of the vane frame, a circumferential analysis of an approximate vane geometry, including the pylon, was performed. This analysis indicated, for uniform flow at vane inlet, that the vane discharge Mach number was approximately constant circumferentially and that the discharge air angle was nearly linear circumferentially between the pylon wall angles. Figure 22, an unwrapped cross section at the ID, shows the flowfield calculated by this analysis. The specific design criteria selected for the layout of the five-vane geometry groups was to change the average discharge vector diagram with zero swirl to vector diagrams with $\pm 5^\circ$ of swirl and $\pm 10^\circ$ of swirl.

The meanline shapes for each of the five-vane groups vary. For the vane group which overturns the flow by $+10^\circ$ the meanline is approximately a circular arc. As a result of passage area distribution and choking considerations, the meanline shape employed in the forward 25% chord region of this vane group was retained for the other four groups.

The incidence angle for all vane groups was the same and was selected for the group with the highest camber. A correlation of NASA low-speed cascade data was the starting point for the incidence selection. Over the outer portion of the vane, where the inlet Mach number is lower, the incidence angles were slanted to the low side of the correlation. This was done in consideration of the reverse thrust mode of operation for the UTW fan. In this mode, the OGV's impart a swirl counter to the direction of rotor rotation. Additional vane leading edge camber tends to increase the counterswirl and therefore the pumping capacity of the fan. In the inner portion of the vane the incidence angles are higher than suggested by the correlation because of the higher inlet Mach number. Also, in the reverse mode of operation, this reduction in vane leading edge camber in the ID region reduces the swirl for that portion of the fluid which enters the core engine and tends to reduce its pressure drop.

Figure 21. Vane-Frame Nominal Vane Configuration.

Figure 22. Vane Frame Unwrapped Section at I.D.

ORIGINAL PAGE IS
OF POOR QUALITY

The deviation angle for each of the five vane groups was calculated from Carter's Rule as described for the rotor. The portion of the meanline aft of the 25% chord point approximates a circular arc blending between the front circular arc and the required trailing edge angle. For the vane group which underturns the flow by 10° the aft portion of the blade has little camber. Figure 23 shows an unwrapped cross section at the ID of two of the 10° over-cambered vanes and two of the 10° under-cambered vanes adjacent to the pylon. Note that the spacing between the pylon and the first under-cambered vane is 50% larger than average. This increased spacing was required to open the passage internal area, relative to the capture area, to retrieve the area blocked by the radial drive shaft envelope requirements.

Table V gives the detailed coordinate data for the two vane geometries and the pylon leading edge geometry shown in Figure 23. The coordinate data for the nominal vane geometry at three radial locations is also given in this table. The vane coordinates are in inches.

The radial distributions of camber and stagger for the nominal and two extreme vane geometries are shown in Figure 24. The radial distributions of chord and solidity for the nominal vane are shown in Figure 25. The design held the leading and trailing edge axial projection common for all five groups which results in slightly different chord lengths for the other four vane types.

SECTION 3.0

OTW FAN MECHANICAL DESIGN

3.1 OTW FAN ROTOR SUMMARY

The OTW experimental fan has 28 fixed-pitch metal blades with a 180 cm (71 in.) fan tip diameter similar to that of the UTW fan. This rotor is shown in Figure 26. The conceptual design of this fan is based on using composite fan blades, but metal blades will be used for reasons of economy and low risk. The conceptual composite bladed design dictates the absence of blade shrouds, determines the number of fan blades, and affects the sizing of such parameters as the blade solidity, reduced velocity, and leading edge thickness. In the flight engine, composite blades would be substituted for the metal blades without aerodynamic change or compromise in the composite blade mechanical design. While the demonstrator fan disk is heavier than the composite bladed flight weight disk, it reflects a flight configuration in both design criteria and material selection. A comparison between the experimental and flight OTW fan design criteria is given in Table VI.

The OTW fan has both a forward rotating spinner and aft flowpath adapter. The inner flowpath formed by these two parts and the blade platform is identical to the inner flowpath of the UTW fan from a point near the blade trailing edge aft. The tip speed of the OTW fan is about 14% higher than for the UTW Fan. The OTW fan, reduction gear, and fan frame assembly are shown in Figure 27.

3.2 OTW FAN BLADE

The OTW fan blades will be machined 6Al-4V titanium forgings. The steady-state operating stresses in the blade are relatively low, reflecting the relatively low tip speed of this fan. The mechanical design of these blades avoids resonance and fan blade instability in the operating range.

The fan blades are a "low-flexed" design, i.e., the first flexural frequency of the blades is less than two times the per-rev frequency of the fan in its operating speed range. Without a thicker blade root, which would have been aerodynamically unsatisfactory, low-flexing was necessary because of the lack of blade shrouds. This approach, though not common, is used successfully on General Electric's TF34 fan and J79 stage 1 compressor blade and was successful on NASA's Quiet Engine C fan. The first flexural blade frequency Campbell diagram is shown in Figure 28. The frequency of the disk-blade assembly will be somewhat lower than the individual blade frequency (solid curve, Figure 28) due to the flexibility of the supporting fan disk. This allows for some adjustment of the 2 per-rev resonant point during final disk design as shown by the two dashed lines. This resonance crossover will occur below approach fan speed but above flight idle in a region of the performance map not used for steady-state operation. The Campbell diagram for the first three modes is shown in Figure 29. In the absence of frame struts or inlet

guide vanes ahead of the fan, higher order resonances have not been a problem on similar configuration engines such as TF34 and CF6.

Blade "instability" or "limit cycle vibration" can be a problem on fans. It is characterized by a high amplitude vibration in a single mode (normally the first flexural or torsional mode) at a non-integral per-rev frequency. It is not one of the classical airfoil flutter cases and is apparently confined to cascades. Because of the non-linearity in the aerodynamics involved, it has resisted practical solutions by solely theoretical means. Accordingly, General Electric has adopted a semi-empirical "reduced velocity" approach for limit cycle avoidance. Reduced velocity gives a measure of a blade's stability against self excited vibration. This parameter is defined as $V_R = W/bf_t$

where:

b = 1/2 chord at 5/6 span-ft

W = average air velocity relative to the blade over the outer third of the span-ft/sec

f_t = first torsional frequency at design rpm-rad/sec.

The basic criterion used for setting the design of the OTW metal blade was the requirement of having a reduced velocity parameter no higher than 1.5. This allowable range is based on previous testing of a variety of fan configurations in combination with the specific aerodynamic design of the OTW blade.

The design practice is to have the blade stall before instability occurs. Blade instability apparently does not occur once the blades are stalled. The blades are designed so that when the fan is throttled, stall is expected to occur before the empirically predicted blade instability is encountered. The blade stability is affected by varying the blade chord and thickness distribution which changes the reduced velocity parameter. The operating and stall characteristics of this blade are presented in Figure 30 in terms of reduced velocity versus incidence angle. This shows an acceptable blade design in which the throttled fan will stall before encountering the anticipated blade stability limit.

The OTW composite flight blade would have additional stability margin due to the higher stiffness-to-weight ratio possible in composite designs.

The blade will be attached to the disk by a conventional dovetail. The outer flowpath contour will permit individual blade removal in the engine without the necessity of "drop down" dovetail slots. This dovetail will be plasma sprayed with a copper-nickel-indium coating for dovetail fretting protection.

Figure 31 shows a QCSEE OTW fan blade model. The design description of the blade is provided in Table VII and in Figures 32 and 33.

Figure 32. QCSEE OTW Fan Blade Chord Vs. Span.

Figure 33. OTW Fan Blade Maximum Thickness/Chord Vs. Span.

3.3 OTW FAN DISK DESIGN

The OTW fan disk will be machined from a single-piece 6Al-4V titanium forging. An integral cone attaches the ring disk to the main reduction gear shafting. The blades will be retained in the disk dovetail slots by individual steel straps and tangs on the blades. The spinner and aft flowpath adapter attach to flanges on the OD of the disk rim as shown in Figure 34.

The fan disk is designed for a burst margin of 141% of the maximum cycle speed and for a low-cycle fatigue life in excess of 36,000 flight hours.

3.4 OTW FAN SPINNER

The OTW spinner and aft flowpath adapter will be fabricated from the same 6061 aluminum forgings used for corresponding parts on the UTW fan. Fan balance can be performed without removing the spinner by means of radial spinner balance weights, and the blades can be individually removed and replaced in the field by removing the forward spinner only. Access holes in the aft adapter permit unbolting the number one bearing support cone and pulling the disk and main reduction gear as a complete package. Since the OTW fan does not have a pitch change mechanism, the forward spinner cap also provides access for a visual inspection of the main reduction gear.

Figure 34. OTW Fan Rotor.
